There are a small number of published cases of cerebral venous thrombosis (CVT) associated with anabolic androgenic steroids (AAS). We present the case of a 27-year-old man who was admitted to the emergency room with a severe holocranial headache, nausea, vomiting, photophobia, and diplopia. He had no relevant past medical history, but he had been taking anabolic steroids for 1 year. The examination revealed papilledema and bilateral sixth nerve palsy. The computed tomography venography documented thrombosis of the left transverse and sigmoid sinuses. The patient was started on anticoagulant therapy with gradual improvement. The workup ruled out other causes of CVT. Despite the uncertainty about the exact mechanism by which AASs promote thrombosis, our case supports the conviction that high-dose and long-lasting AAS use should be considered a possible cause of CVT. Accordingly, it is of utmost importance to inquire about AAS use in case of suspected CVT.

## Keywords

Anabolic androgenic steroids, cerebral venous thrombosis, steroid abuse

Cerebral venous thrombosis (CVT) is a rare condition.<sup>1-3</sup> While thrombophilias, contraceptive pill, hormonal replacement therapy, and neoplasms are well-established predisposing factors, steroid use is a less-common possible risk factor, particularly with regard to anabolic androgenic steroids (AAS).<sup>1-4</sup>

We intend to describe what is known about AAS and present a case of CVT associated with AAS use in a young patient.

## Case presentation

A 27-year-old man was admitted with a severe holocranial headache, nausea, vomiting, photophobia, and diplopia, which had begun 3 days before. He had no relevant past medical antecedent, no previous migrainous headache, nor any pertinent family history of hypercoagulability. However, he had been taking AASs for 1 year to increase muscle mass (intramuscular testosterone weekly, in addition to 400 mg of oxymetholone and 300 mg of nandrolone daily). On examination he had papilledema and bilateral sixth nerve palsy. Blood tests revealed thrombocytosis with 263,000 platelets/mm<sup>3</sup> without other alterations on hemogram like polycythemia. Computed tomography venography documented thrombosis of the left transverse and sigmoid sinuses (*Figures 1 and 2*). The workup ruled out other causes of CVT, such as hereditary thrombophilia, infection, or neoplasia. Autoimmune diseases and vasculitis syndromes were ruled out by appropriate investigations (e.g., screening for antinuclear antibodies [ANA], antiphospholipid antibodies [APLA], antineutrophil cytoplasmic antibodies [ANCA], cytoplasmic and perinuclear ANCA [cANCA and pANCA]). Vitamin B12, folic acid, and serum homocysteine levels were normal.

The patient was started on anticoagulant therapy with enoxaparin 1 mg/kg every 12 hours. A combination of analgesics and acetazolamide were introduced because of refractory headache. The follow-up magnetic resonance imaging, performed 6 months later, showed resolution of thrombosis.

## Discussion

There are two main types of steroids, namely corticosteroids and AASs; the latter carrying a greater risk of thrombosis. Since their synthesis in 1935, AASs began to be widely consumed: firstly, by the elite athletes to improve their sports performance, and then by the general population, especially the younger, with the purpose of increasing muscle mass as well as a recreational drug, disregarding their harmful effects.<sup>5-6</sup> In fact, AASs are synthetic derivatives of testosterone with a strong anabolic effect and only residual androgenic action.<sup>7</sup> For that reason, they are used to treat several medical conditions, namely many forms of anemia, especially aplastic anemia; acute and chronic wounds; renal failure (in combination with recombinant human erythropoietin); protein-calorie malnutrition

Figure 2: Magnetic resonance imaging-documented thrombosis of the left transverse and sigmoid sinuses

with associated weight loss, such as HIV-associated wasting syndrome; and cancer-associated cachexia. AASs approved by the US Food and Drug Administration, and their respective common dosages, are listed in *Table 1*.

Notwithstanding their benefits, the chronic use or abuse of AASs can cause several pathologic alterations, including hepatic, cardiovascular, reproductive, musculoskeletal, endocrine, renal, immunologic, and hematologic dysfunction, as well as psychological and psychiatric effects. Indeed, sudden cardiac death, suicide, and violent deaths have been reported to be more frequent than in the population in general in individuals with a history of long-term AAS use.<sup>8-16</sup>

Table 1: Anabolic androgenic steroids approved by the US Food and Drug Administration

	Administration form	Dosage	Androgenic effect	Anabolic effect
Nandrolone decanoate	Intramuscular	50–100 mg once a week	Residual	Very high
Oxandrolone (Oxandrin®)	Oral	2.5 mg two to four times a day	Low	High
Stanozolol (Winstrol)	Oral	2 mg three times a day	Medium	Medium
Oxymetholone (Anadrol®-50)	Oral	1–5 mg/kg of body weight per day	High	High

Table 2: Published anabolic androgenic steroid-associated cerebral venous thrombosis cases

Publication	Gender/age	Anabolic androgenic steroid	Use duration	Outcome
Jaillard et al. 1994 <sup>19</sup>	M, 31	Not specified	Not specified	Favorable
Chu et al. 2001 <sup>17</sup>	F, 40	Oxymetholone	2 years	Favorable
Sahraian et al. 2004 <sup>20</sup>	M, 22	Nandrolone	5 months	Favorable
Sveinsson et al. 2013 <sup>22</sup>	M, 21	Methandrostenolone	4 months	Favorable

From the neurological point of view, some CVT cases have been reported in the last decade among AAS consumers, and there are probably many non-diagnosed cases due to the illegality of its use. AAS-associated CVT cases published until now are listed in *Table 2*, highlighting the type of AAS consumed, duration of use, and outcome of CVT.<sup>17-22</sup> The exact mechanism by which AASs cause CVT is unknown; however, the existing evidence suggests that they promote fluctuations on the hemostatic system from an antithrombotic to a prothrombotic state.

Additionally, *in vitro* experiences have shown that AASs can favor platelet aggregation.<sup>1-3,19</sup>

Despite the small number of published cases and the uncertainty about the exact mechanism by which AASs promote thrombosis, the fact that

the patient had no medical relevant antecedents or risk factors, associated with the complete recovery after therapy, supports the conviction that high-dose and long-lasting AAS use should be considered a possible cause of CVT. Accordingly, it is very important to inquire about AAS use in cases of suspected CVT. □
